

Social Media and the News Cycle

- **Project Goal:** Build a real time analytics layer for media outlets to assess their influence within social media, including trend detection, brand protection, and awareness of one's own relationship to the social-media universe.

A Core Engine for News Outlet Social Media Investigations

Desired Insights

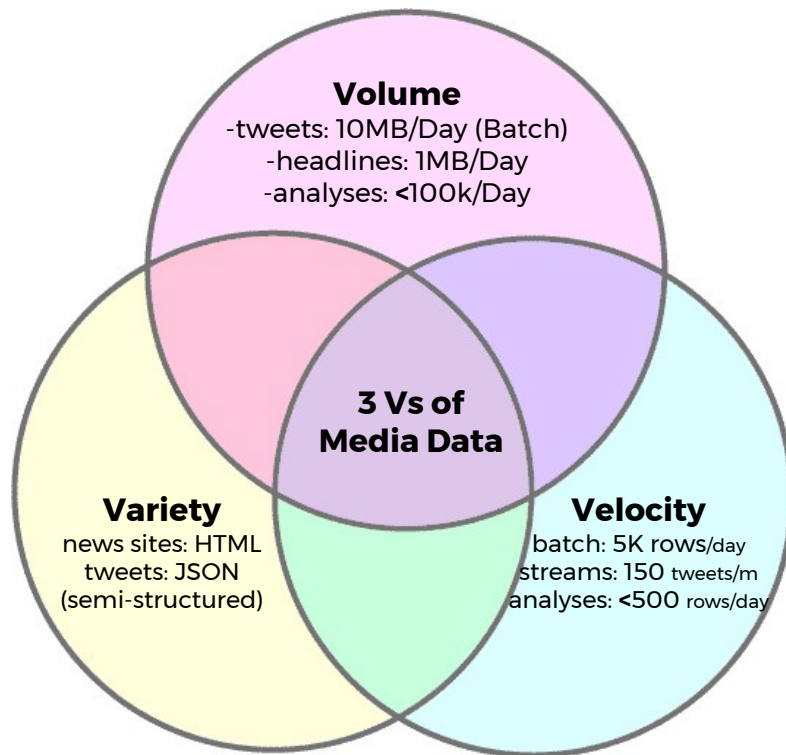

Data Characteristics

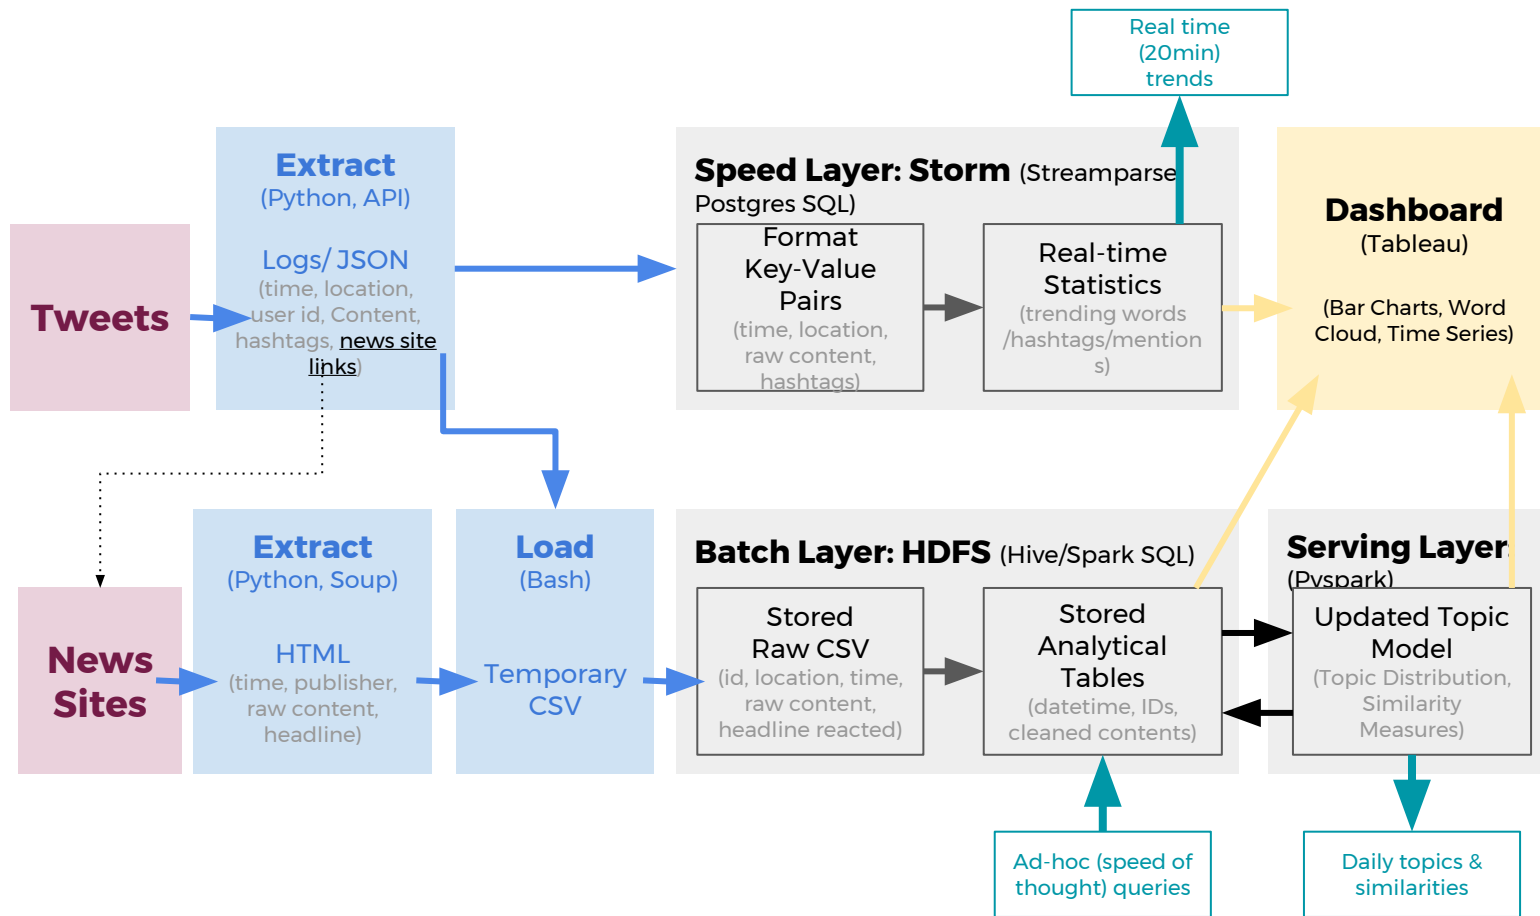

- **Realtime**
 - Trending words
 - Trending @mentions
 - Trending hashtags
- **Every Day**
 - Tweets Topic Summary
 - Headlines Topic Summary
 - Correlation(tweets , headlines)
- **Ad hoc**
 - Popular mentions over time
 - Top influencers by Day/Month/Year
 - Hashtag trends over time
 - Top mentions by top influencers
 - Usual words by top influencers

Data Challenge :

Need an architecture that scales-out for high volume in the long run and ingest high velocity of data

Scale-out solution: Lambda Architecture

Alternatives and Tradeoffs

- **Ingestion and ad hoc queries**

- Structured Data Store over HDFS
 - More efficient retrieval for queries
 - Less flexibility to manipulate data
 - Less compatible with HTML or JSON (semi-structured)
 - Need Sqoop set up if moving to another HDFS
- Postgres over Hive or Spark SQL
 - Schema-on-write over schema-on-read: optimized to speed retrieval
 - Efficient Indexing :Fast lookups, lower cost reads
 - Easy to examine query plan
 - Enable insertion and updates
 - ACID database
 - Limited number of records/table
 - Not distributed without sharding
 - Schema modification : expensive to migrate
 - Can cause duplicate materialization
 - Our data is non-transactional and semi-structured
 - Streamed tweet formats are unstable, impossible to impose uniform schema

- **Machine Learning**

- Python over Pyspark
 - Intuitive, easily incorporated with EDA tools
 - Data transformation can be examined more visually pandas
 - Cannot train models with large number of records without RDD advantage
- R over Pyspark
 - More built-in statistical tools, much easier for model evaluation
 - Single-threaded, only deal with small data problems
 - Distributed R still new in development
- Scala over Pyspark
 - Better MLib support in scala
 - New language barrier

- **Streaming**

- Twitter Heron over streamparse
 - backpressure mechanism, typology scheduling and manage performance by metrics
 - Extra setup time
- Pyspark D-stream over streamparse
 - Can Run interactively
 - Query over a window of several batches
 - Distributed storage (RDDs)
 - Stateful transformations with list comprehensions
 - Less Stable
- Postgres over HDFS+Hive for real-time queries
 - Faster queries that favor memory
 - Need migration to HDFS for more persistent storage

Justifications, Tradeoffs

- **Ingestion and ad hoc queries**

- Scraping and Quality check with Python
 - Compatible with most scraping, and parsing libraries
 - Able to handle our velocity of data
 - Intuitive exception/error management
- HDFS Storage
 - Easy to scale-out storage with more nodes
 - Compatible with Hive and Pyspark mapreduce, distributed computing jobs
 - Compatible with Spark SQL for speedy queries
 - Resilient nodes and data recovery
 - Higher cost for retrieval
 - Prone to IO bound
- Spark SQL or Hive for interactive queries
 - Raw data can be subjected to varying interpretation
 - Schema can mutate over-time for new analyses
 - Spark SQL can cache some table for faster reuse
 - Higher costs to read
 - No implicit guarantees about data quality/contents

- **Machine Learning**

- Pyspark
 - Can push large amount of data through feature extraction and model training pipeline
 - Advantage of RDDs for distributed model training
 - List comprehension similar to python
 - Much harder to debug erroneous RDD processes

- **Streaming**

- Streamparse
 - Support parallelism by specifying instances in typology code
 - Easy to setup and stable
 - No backpressure mechanism, bad hosts can introduce error when running typology
 - Nimbus master node is a single point of failure
 - Inappropriate use of zoo-keeper for too many writes cause overloading issues

- **Visualization**

- Tableau
 - Intuitive Interface
 - Enable connection to real-time data through Hive server
 - Take advantage of Data Cubes for fast results display
 - Limited number visualization formats and manipulation of granularities

Further Developments

• Profile Twitter #fakenews Users

- Label tweets and users using ML model real-time
- Resources/Technology
 - Pyspark 2.2.0 to enable LDA model transformation
 - Convert to Pyspark D stream to outputs streams as RDDs, then feed into Pyspark MLlib

• Long term Investigative Report

- Identify influential twitter users and news agencies for the Trump administration
- Resources/Technology
 - Migrate data over to S3 storage, only spin-up Hadoop clusters for latest datasets or new analyses over old data
 - Consistently run the system for another 42 months

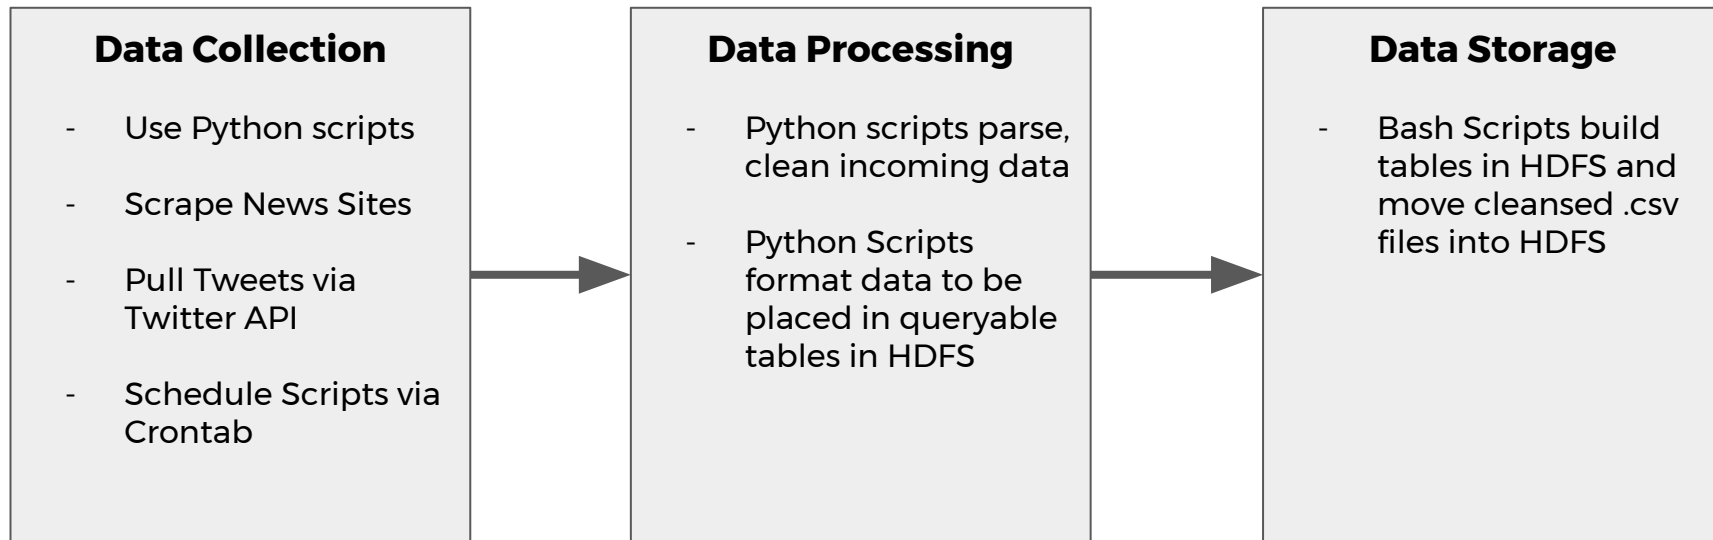

• Working Real-time Visualization

- Use Hive server for real-time Tableau view
- Resources/Technology
 - Work out stable EC2 to local machine connection through Hive server

**For the following slides, please refer to
the video for a full technology demo**

    cosine_sim = cosine_similarity(headlines_vec, tweets_vec)
```

```
    return(headlines_topics, tweets_topics, cos_sim)
```

Insights from Machine Learning Layer (1/2)

Use cosine similarities compare how well headlines from each news agency is reacted by tweets.

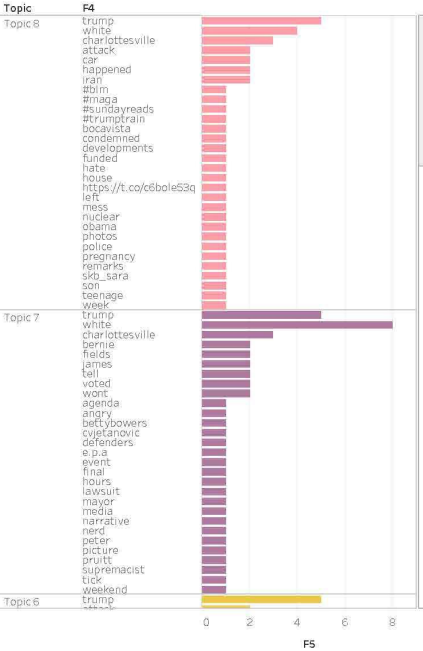

Examine the inferred topics by the dates to study change of topics.
